August 18-21, 2014: Day 1

### Basic subroutine programming

#### Goal

- Show the basics of proper subroutine programming
- Advantages, pitfalls
- Examples in R
- Tomorrow: generalization and differences in other programming languages

### Control structures in programming languages

#### Mostly generic

- ▶ if, else: testing a condition [R, SAS]
- for: execute a loop a fixed number of times [R, in SAS: do]
- while: execute a loop while a condition is true [R,SAS]
- until: execute a loop until a condition is true [SAS]
- repeat: execute an infinite loop [R]
- break: break the execution of a loop [R, SAS]
- next: skip an interation of a loop [R]
- return: exit a function [R]

#### ... in R

```
1 if(<condition>) {
2 ## do something
3 } else {
4 ## do something else
5 }
6 if(<condition1>) {
7 ## do something
8 } else if(<condition2>) {
9 ## do something different
10 } else {
11 ## do something different
12 }
```

#### ... in R

```
1 if(<condition>) {
2 ## do something
3 } else {
4 ## do something else
5 }
6 if(<condition1>) {
7 ## do something
8 } else if(<condition2>) {
9 ## do something different
10 } else {
11 ## do something different
12 }
```

#### ... in SAS

```
1 if (<condition>) then do;
2 ## do something
3 end; else do;
4 ## do something else
5 end;
6 if (<condition1>) then do;
7 ## do something
8 else if (<condition2>) then do;
9 ## do something different
10 end; else do;
11 ## do something different
12 end:
```

Run through a fixed sequence of numbers (or in R, a sequence of vectors)

Run through a fixed sequence of numbers (or in R, a sequence of vectors)

#### simple loop in R

```
for(i in 1:10) {
print(i)
}
```

Run through a fixed sequence of numbers (or in R, a sequence of vectors)

#### simple loop in R

```
1  for(i in 1:10) {
2  print(i)
3  }
```

#### ... in SAS

```
1 do i = 1 to 10;
2 put i;
3 end:
```

Across programming languages, some flexibility:

#### Across programming languages, some flexibility:

#### Equivalent loops in R

```
x <- c("a", "b", "c", "d")
for(i in 1:4) {
   print(x[i])
}
for(i in x) {
   print(i)
}
for(i in x) {
   print(i)
}
for(i in 1:4) print(x[i])</pre>
```

#### ... in SAS

```
1 do i = 1 to 10;
2 put i;
3 end;
```

### Interrupting loops

#### How a loop ends

- at the end
- by resetting the counter to the end value, or by setting the looping condition to its exit value explicitly
- ▶ when it encounters a break (for repeat loops in R)

### What do we loop over?

#### Within the loop, something is done

```
for (i in 1:100000) {
    ## do something here
    # stuff (1 line)
    # stuff (2nd line)
    # done
}
```

### What do we loop over?

#### Within the loop, something is done

```
1 for (i in 1:100000) {
2  ## do something here
3  # stuff (1 line)
4  # stuff (2nd line)
5  # done
6 }
```

#### What if that is really complicated?

```
for (i in 1:100000) {
2  ## do something really complicated here (398 lines)
3 }
```

#### Breaking into discrete chunks

```
for (i in 1:100000) {
## do something really complicated here
## (398 lines)
```

#### Breaking into discrete chunks

```
for (i in 1:100000) {
## do something really complicated here
## (398 lines)
```

In the previous example, this was unwieldy (which loop are you closing on line 400?)

#### Breaking into discrete chunks

```
1 for (i in 1:100000) {
2 ## do something really complicated here
3 ## (398 lines)
```

We can start by breaking out the complicated stuff into a well-defined subroutine. In the previous example, this was unwieldy (which loop are you closing on line 400?)

#### Breaking into discrete chunks

```
1 for (i in 1:100000) {
2 ## do something really complicated here
3 ## (398 lines)
```

We can start by breaking out the complicated stuff into a well-defined subroutine. In the previous example, this was unwieldy (which loop are you closing on line 400?)

```
1 for (i in 1:100000) {
2  ## new subroutine
3  do_something_complicated(args=something)
4  ##
5 }
```

### Subroutines, procedures, etc.

#### What do you call a subroutine?

"The same things in different [programming] languages can have different names. Programs, Procedures, Functions, **Subroutines**, Subprograms, Subqueries ... these words all have very similar meanings. [...] We can call an object, it executes and performs a complex process. Whether that object is called any one of the above list depends on what programming language it is written in, whether a human being can call it, or whether it has to be called by another program or one of the other names on the list."

Source

### An practical overview of subroutine programming

#### We will use R...

... but expand to cover what this might look like in SAS (macros), Stata (programs, ado files), Matlab (functions) tomorrow.

... use this as a building block to scale to HPC.

#### You already use them!

Much functionality in SAS, Stata, Matlab, R is implemented as a subroutine:

- proc import in SAS (compare call to log file)
- Most statistical functions in Stata (regress used earlier is actually in ../ado/base/r/regress.ado)

You can create them too!

#### Functions in R

#### R objects of class "function"

```
1  f <- function(<arguments>) {
2  ## do something here
3 }
```

- Functions can be arguments to other functions
- Functions can be nested (even recursive)
- Functions can have named arguments with default values, or missing values

We draw on Peng's "Computing for Data Analysis, Week 2" for this section.

### Basic examples

#### Let's start with a simple example

```
1  # This is a very simple function
2  # It simply draws a draws from a normal with mean=b
3  f <- function(a=1,b=0) {
4     rnorm(a,mean = b)
5 }</pre>
```

### Basic examples

#### Let's start with a simple example

```
1  # This is a very simple function
2  # It simply draws a draws from a normal with mean=b
3  f <- function(a=1,b=0) {
4     rnorm(a,mean = b)
5 }</pre>
```

The function is defined, has two arguments with default values, and a really short name.

### Basic examples

#### Let's start with a simple example

```
1  # This is a very simple function
2  # It simply draws a draws from a normal with mean=b
3  f <- function(a=1,b=0) {
4     rnorm(a,mean = b)
5 }</pre>
```

The function is defined, has two arguments with default values, and a really short name.

#### Results

### Defining function arguments

Functions have *named* arguments which potentially have *default* values.

- The formal arguments are the arguments included in the function definition
- Not every function call in R makes use of all the formal arguments
- Function arguments can be missing, or can have default values

### Function arguments at invocation

Function arguments can be passed by position (*positional*) or by explicit name (in which case, position doesn't matter).

Listing 1: Equivalent calls

```
1 > set.seed(10)

2 > mean(f(b=5,a=10))

3 [1] 4.509343

4 > set.seed(10)

5 | mean(f(a=10,b=5))

6 [1] 4.509343

7 > set.seed(10)

9 | mean(f(10,5))

9 | 11 4.509343
```

However, it is **good practice** to use *named* arguments, as they make use of the function (especially when more complex) easier and more transparent.

### Lazy evaluation

#### Arguments can remain unused:

b was never used.

## Arguments can be faulty, but don't lead to problems until used

```
f <- function(a, b) {
print(a)
print(b)
}
> f(45)  # note no value provided for b
[1] 45
Error in print(b) : argument "b" is missing, with no default
>
```

The absence of a value for b only led to an error at the time it was called.

#### Scope of functions

```
f <- function(a,b) {
    print(a)
    print(c)
    c <- paste(a,b)
    print (c)
}</pre>
```

#### Try it out:

#### Scope of functions

```
f <- function(a,b) {
    print(a)
    print(c)
    c <- paste(a,b)
    print (c)
}</pre>
```

#### Try it out:

```
1 > f(c('a'),c('b'))
2 [1] "a"
3 function (..., recursive = FALSE) .Primitive("c") <== ERROR!
4 [1] "a_b"
```

#### What happened?

 $_{\rm C}$  was not defined, leading to the error on line 4. Line 5 reports what happens to  $_{\rm C}$  once it is defined.

#### Understanding the scope

```
5 > c <- c('Nothing')
6 > f(c('a'),c('b'))
7 [1] "a"
8 [1] "Nothing"
9 [1] "a_b"
```

So what value does c now have?

#### What happened?

 $_{\rm C}$  was not defined, leading to the error on line 4. Line 5 reports what happens to  $_{\rm C}$  once it is defined.

#### Understanding the scope

```
12 > c <- c('Nothing')

13 > f(c('a'),c('b'))

14 [1] "a"

15 [1] "Nothing"

16 [1] "a_b"
```

#### So what value does c now have?

```
17 > print(c)
18 [1] "Nothing"
```

#### Understanding the scope of variables

► In the example, c was defined both inside the function and outside.

#### Other programming languages

Each programming language has a different way of handling these. Take care to read up on it.

#### Understanding the scope of variables

- ► In the example, c was defined both inside the function and outside.
- ► R took the "global" value of c ...

#### Other programming languages

Each programming language has a different way of handling these. Take care to read up on it.

#### Understanding the scope of variables

- In the example, c was defined both inside the function and outside.
- ▶ R took the "global" value of c ...
- until the function defined it, at which point it took a new value internal to the function

#### Other programming languages

Each programming language has a different way of handling these. Take care to read up on it.

#### Understanding the scope of variables

- ▶ In the example, c was defined both inside the function and outside.
- R took the "global" value of c ...
- until the function defined it, at which point it took a new value internal to the function
- ... which was only used until the function ended. The "global" value had not changed.

#### Other programming languages

Each programming language has a different way of handling these. Take care to read up on it.

## Searching for variables (and functions)

- The global environment or the user?s workspace is always the first element of the search list and the base package is always the last.
- The order of the packages on the search list matters!
- User?s can configure the order of packages as they get loaded on startup ...
- When a user loads a package with library the namespace of that package gets put in position 2 of the search list (by default) and everything else gets shifted down the list.

# Scoping (name resolution) rules

## Lexical scoping

**Lexical** (or **static**) resolution can be determined at compile time, and is also known as **early binding** 

## Dynamic scoping

**Dynamic** resolution can in general only be determined at run time, and thus is known as **late binding**.

Most modern languages use lexical scoping for variables and functions, though de facto dynamic scoping is common in macro languages, which do not directly do name resolution. [1]

# Scoping rules

#### Back to R

```
\begin{array}{l} f <\!\!- function(a,b) \; \{\\ print(paste(a,b))\\ print(c) \end{array}
```

- ▶ Named (formal) arguments (a, b) are always local
- ► Free variables (not defined in the call) (c) are subject to scoping rules

# Lexical scoping in R

#### Lexical scoping in R means that

the values of free variables are searched for in the environment in which the function was defined.

#### What is an environment?

- An environment is a collection of (symbol, value) pairs, i.e. x is a symbol and 3.14 might be its value.
- Every environment has a parent environment; it is possible for an environment to have multiple ?children?
- A function + an environment = a closure or function closure.

## Safe use of scoping

### Define all variables as arguments

To avoid confusion about where variables are defined, unless you have a good reason to deviate from this

- Define all variables as arguments to the function
- ▶ In other languages, explicitly define the scope of a variable

## Scope of macro variables in SAS Define a similar program in SAS

```
%macro myprogram(a=,b=);
%let c=&a.&b.;
%put &c.;
%mend;
```

## Scope of macro variables in SAS

## Define a similar program in SAS

```
%macro myprogram(a=,b=);
%let c=&a.&b.;
%put &c.;
%mend:
```

#### Call it and assess where c comes from:

```
%myprogram(a=a,b=b);
%put &c.;
%let c=Nothing;%put &c.;
%myprogram(a=a,b=b);
%put &c.;
```

#### with results

```
%macro myprogram (a=,b=);
    %let c=&a.&b.;
    %put &c.;
    %mend;
    %myprogram(a=a,b=b);
ab
WARNING: Apparent symbolic reference C not resolved.
     %put &c . :
&c.
8
    %let c=Nothing;%put &c.;
Nothing
    %myprogram (a=a, b=b);
ab
10
    %put &c.;
ab
```

#### Better:

```
1  %macro myprogram(a=,b=);
2  %local c;
3  %let c=&a.&b.;
4  %put &c.;
5  %mend;
6  %let c=Nothing;
7  %myprogram(a=a,b=b);
ab
8  %put &c.;
Nothing
```

#### Differences that need to be taken into account

- Scoping rules can be leveraged to improve optimization (see Peng's Coursera course and others)
- ► The use of scoping differs across languages (what is feasible in R cannot be simply translated into Java or SAS or Stata)

## Naming is important

Naming is important - both of functions and of arguments: Compare the following two functions:

```
1    f <- function(a,b,c) {
2         x <- sample(y,c)
3         lm(a ~ b , data=x )
4    }

and

1    sample_reg <- function(lhs,rhs,samplesize=10,data=) {
2         subset <- sample(data,samplesize)
3         lm(lhs ~ rhs , data=subset )
4    }</pre>
```

Give functions and variables meaningful names

## Robustness is important

Think about backward compatibility (and your program library). Say you first used this:

## Robustness is important

Think about backward compatibility (and your program library). Say you first used this:

```
1     sample_reg <- function(lhs,rhs,samplesize=10,data=) {
2         subset <- sample(data,samplesize)
3         lm(lhs ~ rhs , data=subset )
5         sample_reg(earnings,education,5,data=cps)</pre>
```

Now you extend your model

## Robustness is important

You should either give your function a different name, or make the call robust to both the "old" way and the "new" way:

which will work for both calls...

Intro Basics VCS Subroutines

The power of functions

# The power of functions

## Why bother with functions?

- Initial example: putting 398 command lines into separate file (ease of use)
- Expansion on that: re-using the function across multiple projects (function library)
- Your function is a complete specification. You know want to vary or perturb all 25 parameters slightly, for robustness checks.

```
1     for (i in 1:1000) {
2         for (j in 1:1000) {
3             my_regression(model=base, xi=i, xj=j)
4         }
5     }
```

## The power of functions

### Why bother with functions?

You want to database the results:

```
1     for (i in 1:1000) {
2         for (j in 1:1000) {
3             results_db[i,j]=my_regression(model=base, xi=i, xj=j) }
4         }
5     }
```

## The power of functions

### The ultimate power of functions: scaling

You want to speed the whole thing up by parallelizing:

```
library(doMC)
registerDoMC()
foreach (i = 1:1000, .combine=cbind) %dopar% {
    for (j in 1:1000) {
        results_db[i,j]=my_regression(model=base, xi=i, xj=j)
}
}
```

which will run 1000 parallel threads, on as many cores as you can. (see doMC vignette or the help in your Rstudio installation)

# Take-away

## Major points

- Subroutines are a powerful tool to write clean, understandable code
- Subroutines (functions, macros, programs) are present in some form in all statistical programming languages
- Use consistent, clear naming
- Use robust subroutines, expanding them into a library that you can use and share across projects
- Clean subroutines are a critical component to scaling your analysis (parallelization)

## Take-away

#### Additional items

- learn how to debug (different in each language, also critical to scaling)
- subroutines don't magically make your code efficient they allow you to figure out which portions are not
